Current-mode Quadrature Oscillator using CCCCTAs with Non-interactive Current Control for CO, FO and Amplitude

Adirek Jantakun

Department of Electronics and Telecommunication Engineering, Faculty of Engineering, Rajamangala University of Technology Isan, Khonkaen Campus, Khonkaen, Thailand

Abstract: This paper presents a current-mode quadrature oscillator with amplitude controllability. The proposed circuit consists of two current controlled current conveyor transconductance amplifiers, two grounded capacitors and one grounded resistor. The condition of oscillation, frequency of oscillation and amplitude of output current can be independently controlled with electronics method via DC bias current. In addition, the proposed oscillator has high impedance of outputs ports which facilitates easy driving an external load without additional current buffers. It also uses all grounded passive elements which suitable for implementation in the integrated circuit. The theoretical results are verified by PSPICE simulation and experimental results that well conform to the theoretical anticipation.

Keywords: Current-mode; Quadrature Oscillator; Current Controlled Current Conveyor Transconductance Amplifier; Grounded Elements

1 Introduction

An oscillator which provides two sinusoidal signals with 90° phase difference, or well known as quadrature oscillator, has been continuously proposed since it plays an important role and has been widely applied in various applications such as communication, instrumentation, measurement and signal processing, etc [1-4]. Especially in communication systems, the sinusoidal oscillator is frequently used to generate the carrier signal for modulation system [5-6] such as AM, FM, ASK etc. Normally, the oscillator would generate the signal without amplitude controllability. So in some applications which need the exact amplitude, the amplifier circuit is required, causing the complicated circuit. Recently, the portable electronics devices which run on compact batteries have been necessary to reduce voltage power supply and power consumption. These requirements call for the development of current-mode circuit designs due to their potential advantages such as inherently wide bandwidth, higher slew-rate, greater linearity, wider dynamic range, simple circuitry and low power consumption [7-8].
Several quadrature oscillators have been proposed in the literature [9-29]. A lot of them focus on the use of electronically adjustable active building blocks (ABB), such as, current controlled current conveyor (CCCII), current conveyor transconductance amplifier (CCTA), current controlled current conveyor transconductance amplifier (CCCCTA), differential voltage current conveyor or transconductance amplifier (DVCCCTA), current follower transconductance amplifier (CFTA) and current controlled current follower transconductance amplifier (CCCFTA). Some parameters (such as transconductance or parasitic resistance) of these ABBs are tuned by external current or voltage which is easy to control by microcontroller or microcomputer. The review of these oscillator topologies is as follows. The oscillators in Ref. [9-30] use grounded capacitor which is attractive for integrated circuit implementation. In Ref. [9-10], the electronic tuning of frequency of oscillation (FO) by adjusted parasitic resistance $R_x$ is achieved. However, the condition of oscillation (CO) is controlled by current gain control, which is not so common [30-31]. CC-CIIs based sinusoidal oscillator was introduced in [11]. The magnitude of sinusoidal output current can be electronically adjusted as well as the frequency of oscillation, but this oscillator circuit employs three CCCIIs and the control of CO is done by adjusting the value of capacitor which is unconventional. The proposed oscillators in [12-14] exhibit advantages in electronic tuning of the FO by the transconductance $g_m$, but the CO is controlled by change the value of passive resistor, which cause addition complication [30-31]. Although electronic adjusting can be used by digital potentiometer, but it is difficult for implementation [31]. The FO in [12, 19-24] is electronically adjusted by the transconductance gain $g_m$. Some oscillators in [17, 25], the FO and CO cannot independently controlled. The circuits in [18-23, 26-27] can be electronically adjusted the CO and FO. The magnitude of sinusoidal output signal in [28] can be electronically adjusted but the FO and CO cannot be electronically adjusted. However, the amplitude of output signal in [9-10, 12-27, 29] cannot be electronically controlled. The comparison of proposed oscillator with previous work is shown in Table 1.

The purpose of this paper is to present the quadrature oscillator using CCCCTAs. The proposed circuit provides the following advantage features:

The current-output signal from high-impedance is easy to drive a load without using a buffering device [30-32]. The proposed circuit uses only grounded capacitors which are advantageous from the point of view of integrated circuit implementation [30-32].

The CO and FO can be electronically and independently controlled.

The amplitude of output current can be controlled via external bias current without effect of the CO and FO, which can provide the AM and ASK signal, widely used in communication systems [32].

Low active and passive sensitivities.

The workability of the proposed sinusoidal oscillator is confirmed via the PSPICE simulation and experiment.

2 Current Controlled Current Conveyor Transconductance Amplifier (CCCCTA)

Since the proposed circuit is based on CCCCTA [15], a brief review of CCCCTA is given in this section. It was modified from the first generation CCTA [8]. The characteristics of the ideal CCCCTA are represented by the following hybrid matrix:

\[
\begin{bmatrix}
  I_x \\
  V_x \\
  I_{x,z} \\
  I_o
\end{bmatrix} = 
\begin{bmatrix}
  0 & 0 & 0 & 0 \\
  1 & R_x & 0 & 0 \\
  0 & 1 & 0 & 0 \\
  0 & 0 & 0 & \pm g_m
\end{bmatrix}
\begin{bmatrix}
  V_y \\
  I_y \\
  I_{y,z} \\
  V_z
\end{bmatrix}
\]  

(1)

For the CCCCTA implemented by a bipolar technology, the parasitic resistance \( R_x \) is given as

\[ R_x = \frac{V_z}{2I_y} \]  

(2)

and transconductance \( g_m \) is given as

\[ g_m = \frac{I_{y,z}}{2V_z} \]  

(3)

The circuit symbol and equivalent circuit of the CCCCTA are illustrated in Fig. 1(a) and (b), respectively.

![Figure 1: CCCCTA (a) schematic symbol (b) equivalent circuit](image)

3 Proposed circuit configuration

The proposed quadrature oscillator is shown in Fig. 2. It consists of two CCCCTAs, two grounded capacitors and one grounded resistor. The quadrature output current ports are \( I_{y_{B1}}, I_{y_{B2}} \) and \( I_o \) is the output current with amplitude controllability. The use of grounded passive element is advantageous from the point of view of integrated circuit implementation [30-32]. Moreover, it is found that the oscillator provides high output impedance which can directly drive a load without buffering devices [30-32]. Using (1) and doing routine circuit analysis, the system characteristic equation can be expressed as

\[ s^2 + \left( \frac{1}{R_1} - \frac{1}{R_{z_2}} \right) s + \frac{g_{m1}}{C_1C_2R_{z_1}} = 0 \]  

(4)

From (4), it can be seen that the proposed circuit can produce oscillations if the condition of oscillation is fulfilled

\[ R_1 = R_{z_2} \]  

(5)

If the above condition of oscillation is satisfied, the circuit produces oscillation with frequency of...
The parasitic resistance $R_x$ and transconductance $g_{m}$ as respectively shown in (2) and (3) into (5) and (6), the CO becomes

$$I_{g1} = \frac{V_c}{2R_i} \tag{7}$$

and the FO is obtained as

$$f_{oa} = \frac{1}{2RV_i} \sqrt{\frac{I_{g1}I_{g2}}{C_iC_s}} \tag{8}$$

It is found that the CO can be electronically controlled through DC bias current $I_{g1}$ without effect of the FO. Also, the FO can be electronically tuned through $I_{g1}$ or $I_{g2}$ without effect of the CO. Consequently, this circuit enables non-interactive current control for both the CO and the FO.

Figure 2: The proposed quadrature oscillator using CC-CCTAs

The ratio between output current $I_{o2}$ and $I_{o1}$ is

$$\frac{I_{o2}}{I_{o1}} = \frac{g_{m1}}{C_2s} \tag{9}$$

It is found that the phase difference of output current $I_{o1}$ and $I_{o2}$ is 90°. However, at oscillation state ($\omega_0=\omega_{osc}$), the relationship of $I_{o2}$ and $I_{o1}$ in (9) is changed to

$$\frac{I_{o2}}{I_{o1}} \bigg|_{\omega=\omega_{osc}} = \frac{C_1g_{m1}R_1}{C_2} \tag{10}$$

Substituting the parasitic resistance $R_x$ and transconductance $g_{m}$ as respectively shown in (2) and (3) into (10), the ratio between output current $I_{o2}$ and $I_{o1}$ becomes

$$\frac{I_{o2}}{I_{o1}} \bigg|_{\omega=\omega_{osc}} = \frac{C_1I_{g1}}{4C_1I_{g1}} \tag{11}$$

It is obvious seen from (11) that the tune of $I_{g2}$ or $I_{g1}$ for controlling the frequency of oscillation causes change of amplitude $I_{o2}$ and $I_{o1}$ during tuning process. When amplitude of $I_{o2}$ or $I_{o1}$ increases the voltage at notes $V_{y1}$ and $V_{z1}$ also increase too. This phenomenon will increase the THD if amplitude reaches high levels due to the limits of dynamical range of CCCCTA. However, this can be alleviated by simultaneously changing $I_{g2}$ and $I_{g1}$ ($I_{g2}=I_{g1}$).

Furthermore, the output current $I_{o3}$ can be obtained as

$$I_{o3} = g_{m2}V_{z2} \tag{12}$$

From (12), the voltage $V_{z2}$ is the sinusoidal signal. It means that the amplitude of sinusoidal signal $I_{o3}$ can

Figure 3: The non-ideal CCCCTA

Figure 4: The internal construction of CCCCTA
be electronically controlled by \( I_{b4} \) without effect of CO and FO. Therefore, if \( I_{b4} \) is a modulating signal, AM and ASK signal can be obtained at \( I_{o3} \). In addition, the output current \( I_{o3} \) port is high-impedance. It is easy to drive a load without using a buffering device.

The sensitivities of active and passive for frequency of oscillation are low as shown in (13)

\[
S_{\delta f} = \frac{1}{2}, \quad S_{\delta c_{i}, \delta a_{i}} = -\frac{1}{2} \tag{13}
\]

4 Non-ideal Analysis

Considering to voltage and current tracking errors, the CCCCTA properties can be written as

\[
\begin{bmatrix}
I_s \\
V_s \\
I_x \\
I_y
\end{bmatrix} =
\begin{bmatrix}
0 & 0 & 0 & 0 \\
\gamma R_s & 0 & 0 & I_s \\
0 & \alpha & 0 & 0 \\
0 & 0 & \pm \beta g_a & V_s
\end{bmatrix}
\begin{bmatrix}
V_s \\
I_s \\
V_s \\
V_s
\end{bmatrix} \tag{14}
\]

Where \( \gamma = \gamma_s / (1 + s / \omega_s) \), \( \alpha = \alpha_s / (1 + s / \omega_s) \) and \( \beta = \beta_s / (1 + s / \omega_s) \). They are frequency-dependence of non-ideal of voltage and current gains, respectively. \( \omega_s \), \( \omega_a \) and \( \omega_b \) are dc non-ideal bandwidths with ideality equal to infinity. \( \gamma_s \), \( \alpha_s \) and \( \beta_s \) are dc non-ideal gains with ideality equal to unity. Moreover, the effect of parasitic resistances and capacitances are also taken into account. The \( C_y \), \( C_z \) and \( C_o \) are parasitic capacitors at \( y \), \( z \) and \( o \) terminals respectively, with ideality equal to zero. The parasitic resistors \( R_y \), \( R_z \), \( R_o \) at \( y \), \( z \) and \( o \) terminals with ideality equal to infinity. These parasitic components of the CCCCTA are shown in Fig. 3.

Re-analysis the circuit in Fig. 2, the characteristic equation is modified to

\[
s^2 + s \left[ \frac{G_d}{C_1} + \frac{G_{d1}}{C_{11}} - \frac{G_{d2}}{C_{12}} \right] + R_s \gamma_a G_o \delta a_{1} + \frac{G_d G_{a1} - G_{d2} G_{a1}}{C_1 C_2} = 0 \tag{15}
\]

Then, the CO and FO of the proposed circuit become

\[
\frac{G_{d1}}{C_2} + \frac{G_{d2}}{C_1} = 0 \tag{16}
\]

And

\[
\omega_{osc} = \sqrt{\frac{G_d \gamma_a G_o \delta a_{1} + G_{d1} G_{a1} - G_{d2} G_{a1}}{C_1 C_2}} \tag{17}
\]

Where \( C_i = C_1 + C_{11} + C_{12} + C_{a1} + C_{a2} \), \( C_{i} = C_2 + C_{a1} \), \( G_d = G_{d1} + G_{d2} + G_{a1} + G_{a2} + G_{R1} \), \( G_{d1} = \frac{1}{R_1} \), \( G_{a1} = \frac{1}{R_{a1}} \), \( G_{d2} = \frac{1}{R_{a2}} \), \( G_{a2} = \frac{1}{R_{a3}} \), \( G_{a3} = \frac{1}{R_{a2}} \), and \( G_{a4} = \frac{1}{R_{a3}} \).

5 Simulation Results

To prove the performances of the proposed oscillator, the PSPICE simulation was performed for examination. The BJT technology was simulated by using the parameters of the PR200N and NR200N bipolar transistors of ALA400 transistor array from AT&T. Fig. 4 depicts the schematic description of the CCCCTA used in the simulations with \( \pm 1.8 \) V power supplies.

![Figure 5: The waveforms of sinusoidal oscillator (a) transient state (b) steady state](image)

The sinusoidal oscillator was designed with \( C_1 = 1 \) nF, \( C_{a1} = 0.47 \) nF, \( R_1 = 1 \) k\( \Omega \), \( I_{b1} = 58 \) \( \mu \)A, \( I_{b2} = 115 \) \( \mu \)A and \( I_{b4} = 10 \) \( \mu \)A. From (7), the bias current \( I_{b4} \) was set nearby \( V_s/2R \), to start-up the oscillation, which is \( I_{b4} = 10 \) \( \mu \)A. The power dissipation of this case is about 4.26 mW. This yields oscillation frequency of 630 kHz. Fig. 5 (a)
and (b) show simulated output waveforms in transient and steady state, respectively. Fig. 6 shows simulated output spectrum, where the total harmonic distortions (THD) of output current $I_{O1}$ and $I_{O2}$ are about 1.00% and 2.21%, respectively.

The simulated result of the proposed circuit serving as an AM generator at $I_{O3}$ is shown in Fig. 7, where $I_{B4}$ was triangular signal with a 50 kHz frequency. It is confirmed that the proposed circuit can easily generate AM signal.

The electronically adjustment of the FO can be demonstrated in Fig. 8 (a), while keeping $I_{B2} = 115 \mu A$ and tuning bias current $I_{B1}$ from 10 $\mu A$-200 $\mu A$. Similarity, Fig. 8 (b) shows the simulation of FO, which remains $I_{B1} = 58 \mu A$ and adjusts $I_{B2}$ from 20 $\mu A$-190 $\mu A$. It is clear seen that the simulation results are in accordance with the theoretical analysis as shown in equation (8). The error of the oscillation frequency stems from the non-ideal parameters as depicted in the Section IV. The amplitude of output current $I_{O1}$ can be exhibited in Fig. 9, when tuning bias current $I_{B1}$ and $I_{B2}$.

6 Experimental Results

To prove the theoretical analysis of proposed oscillator, the experimental results are shown in this section. The circuit for experiment is illustrated in Fig. 10. It was constructed by using commercial ICs, which are AD844A [33] and LM13700N [34]. The values of components in experimental circuit were chosen as $C_1 = 1 \text{nF}$, $C_2 = 0.47 \text{nF}$, $R_1 = 1.1 \text{k}\Omega$, $R_{L3} = 1 \text{k}\Omega$ ($R_{L3}$ was used to measure the output current by an oscilloscope). The intrinsic resistances $R_{x1}$ and $R_{x2}$ are realized by OTA-based grounded resistance simulator with following value

$$R_i = \frac{2V_T}{I_B}$$  \hspace{1cm} (16)$$

From (16) the CO and FO can be rewritten as

$$I_{B3} = \frac{2V_T}{R_i}$$  \hspace{1cm} (17)$$

And

$$f_{osc} = \frac{1}{4\pi V_T} \sqrt{\frac{I_{B1}I_{B2}}{C_1C_2}}$$  \hspace{1cm} (18)$$
The relationship of $V_{o2}$ and $V_{o3}$ is as follows:

$$V_{o2} = \frac{I_{b1}V_{o1}}{2V_TsC_2}$$  \hspace{1cm} (19)

Similarly, the amplitude of output voltage $V_{o3}$ is shown in (20)

$$V_{o3} = \frac{I_{b1}R_{x3}V_{o1}}{2V_T}$$  \hspace{1cm} (20)

The circuit in Fig. 10 was biased with $I_{b1} = 60 \, \mu A$, $I_{b2} = 115 \, \mu A$, $I_{b3} = 56 \, \mu A$, $I_{b4} = 60 \, \mu A$ and ±5 V power supplies. An oscilloscope Rigol model DS1046B [35] was used to measure the output waveforms. The waveform of output signals are shown in Fig. 11 (a) where the FO is about 321 kHz. The calculated value of FO from (18) is about 370.84 kHz. The deviation of FO is suffered from parasitic elements of the CCII, OTA and parasitic element of oscilloscope. Moreover, the parasitic influences of the CCII and OTA are shown in Table 2 and 3, respectively. Fig. 11 (b) exhibits the signals of $V_{o1}$ and $V_{o2}$, which are the phase difference of 90°. Furthermore, the frequency spectrum of output signals by use signal analyzer Agilent Technologies model N9000A [36] shown in Fig. 12, that is the FO is about 320.6 kHz. The parameters in Fig. 12 can be calculated the THD of $V_{o1}$, $V_{o2}$ and $V_{o3}$, which are about 1.73 %, 1.53 % and 1.31 %, respectively. These THD ($V_{o1}$, $V_{o2}$ and $V_{o3}$) are close to the simulation, which are about 1.50 %, 1.27 % and 2.17 %, respectively.

To generate the AM signal, $I_{b4}$ is feed as triangular waveform with 25 kHz of frequency. The voltage of current converter in Fig. 13 is used for this case. Fig. 14 shows the AM signal. It is clearly seen that this result confirms the theoretical analysis as shown in (20).

7 Conclusion

Current-mode quadrature oscillator using CCCCTAs and grounded elements has been presented. The proposed circuit consists of two CCCCTAs, two grounded capacitors and one grounded resistor. The condition and frequency of oscillation are independently adjusted by input bias current of CCCCTAs. Due to high-output impedances, it enables easy driving load without external current buffer. In addition, the amplitude of sinusoidal output signal can be electronically tuned. Moreover, it can provide the AM/ASK signals that are widely used in communication systems [32]. The PSpice simulation and experimental results well conform to the theoretical anticipation.
